Mixing properties of ARCH and time-varying ARCH processes (technical report)

Piotr Fryzlewicz Suhasini Subba Rao

Abstract

There exists very few results on mixing for nonstationary processes. However, mixing is often required in statistical inference for nonstationary processes, such as time-varying ARCH (tvARCH) models. In this paper, bounds for the mixing rates of a stochastic process are derived in terms the conditional densities of the process. These bounds are used to obtain the $\alpha$, 2-mixing and $\beta$-mixing rates of the nonstationary time-varying ARCH($p$) process and ARCH($\infty$) process. It is shown that the mixing rate of time-varying ARCH($p$) process is geometric, whereas the bounds on the mixing rate of the ARCH($\infty$) process depends on the rate of decay of the ARCH($\infty$) parameters. We mention that the methodology given in this paper is applicable to other processes.

Key words: Absolutely regular ($\bar{\alpha}$-mixing) ARCH($1$), conditional densities, time-varying ARCH, strong mixing ($\bar{\alpha}$-mixing), 2-mixing.

2000 Mathematics Subject Classification: 62M10, 60G99, 60K99.

1 Introduction

Mixing is a measure of dependence between elements of a random sequence that has a wide range of theoretical applications (see Bradley (2007) and below). One of the most popular mixing measures is $\alpha$-mixing (also called strong mixing), where the $\alpha$-mixing rate of the nonstationary stochastic process $\{X_t\}$ is defined as a sequence of coefficients $\alpha(k)$ such that

$$
\alpha(k) = \sup_{l \in \mathbb{Z}} \sup_{H \subset \sigma(X_{l+1},X_{l+2},\ldots)} \sup_{G \subset \sigma(X_{l+1},X_{l+2},\ldots)} |P(G \cap H) - P(G)P(H)|.
$$

(1)
\{X_t\} is called \(\alpha\)-mixing if \(\alpha(k) \to 0\) as \(k \to \infty\). If \(\{\alpha(k)\}\) decays sufficiently fast to zero as \(k \to \infty\), then, amongst other results, it is possible to show asymptotic normality of sums of \(\{X_k\}\) (c.f. Davidson (1994), Chapter 24), as well as exponential inequalities for such sums (c.f. Bosq (1998)). The notion of 2-mixing is related to strong mixing, but is a weaker condition as it measures the dependence between two random variables and not the entire tails. 2-mixing is often used in statistical inference, for example deriving rates in nonparametric regression (see Bosq (1998)). The 2-mixing rate can be used to derive bounds for the covariance between functions of random variables, say \(\text{cov}(g(X_t), g(X_{t+k}))\) (see Ibragimov (1962)), which is usually not possible when only the correlation structure of \(\{X_k\}\) is known. The 2-mixing rate of \(\{X_k\}\) is defined as a sequence \(\hat{\alpha}(k)\) which satisfies

\[
\hat{\alpha}(k) = \sup_{t \in \mathbb{Z}} \sup_{H \in \sigma(X_t)} \sup_{G \in \sigma(X_{t+k})} |P(G \cap H) - P(G)P(H)|.
\]

(2)

It is clear that \(\hat{\alpha}(k) \leq \alpha(k)\). A closely related mixing measure, introduced in Volkonskii and Rozanov (1959) is \(\beta\)-mixing (also called absolutely regular). The \(\beta\)-mixing rate of the stochastic process \(\{X_t\}\) is defined as a sequence of coefficients \(\beta(k)\) such that

\[
\beta(k) = \sup_{t \in \mathbb{Z}} \sup_{(H_j) \in \sigma(X_t, X_{t-1}, \ldots)} \sum_i \sum_j |P(G_i \cap H_j) - P(G_i)P(H_j)|,
\]

where \(\{G_i\}\) and \(\{H_j\}\) are finite partitions of the sample space \(\Omega\). \(\{X_t\}\) is called \(\beta\)-mixing if \(\beta(k) \to 0\) as \(k \to \infty\). It can be seen that this measure is slightly stronger than \(\alpha\)-mixing (since an upper bound for \(\beta(k)\) immediately gives a bound for \(\alpha(k); \beta(k) \geq \alpha(k)\)).

Despite the versatility of mixing, its main drawback is that in general it is difficult to derive bounds for \(\alpha(k), \hat{\alpha}(k)\) and \(\beta(k)\). However the mixing bounds of some processes are known. Chanda (1974), Gorodetskii (1977), Athreya and Pantula (1986) and Pham and Tran (1985) show strong mixing of the MA(\(\infty\)) process. Feigin and Tweedie (1985) and Pham (1986) have shown geometric ergodicity of Bilinear processes (we note that stationary geometrically ergodic Markov chains are geometrically \(\alpha\)-mixing, 2-mixing and \(\beta\)-mixing - see, for example, Francq and Zakoïan (2006)). More recently, Tjostheim (1990) and Mokkadem (1990) have shown geometric ergodicity for a general class of Markovian processes. The results in Mokkadem (1990) have been applied in Bousamma (1998) to show geometric ergodicity of stationary ARCH(\(p\)) and GARCH(\(p, q\)) processes, where \(p\) and \(q\) are finite integers. Related results on mixing for GARCH(\(p, q\)) processes
can be found in Carrasco and Chen (2002), Liebscher (2005), Sorokin (2006) and Lindner (2008) (for an excellent review) and Francq and Zakoïan (2006) and Meitz and Saikkonen (2008) (where mixing of ‘nonlinear’ GARCH\((p,q)\) processes are also considered). Most of these these results are proven by verifying the Meyn-Tweedie conditions (see Feigin and Tweedie (1985) and Meyn and Tweedie (1993)), and, as mentioned above, are derived under the premise that the process is stationary (or asymptotically stationary) and Markovian. Clearly, if a process is nonstationary, then the aforementioned results do not hold. Therefore for nonstationary processes, an alternative method to prove mixing is required.

The main aim of this paper is to derive a bound for (1), (2) and (3) in terms of the densities of the process plus an additional term, which is an extremal probability. These bounds can be applied to various processes. In this paper, we will focus on ARCH-type processes and use the bounds to derive mixing rates for time-varying ARCH\((p)\) (tvARCH) and ARCH\((\infty)\) processes. The ARCH family of processes is widely used in finance to model the evolution of returns on financial instruments: we refer the reader to the review article of Giraitis et al. (2005) for a comprehensive overview of mathematical properties of ARCH processes, and a list of further references. It is worth mentioning that Hörmann (2008) and Berkes et al. (2008) have considered a different type of dependence, namely a version of the m-dependence moment measure, for ARCH-type processes. The stationary GARCH\((p,q)\) model tends to be the benchmark financial model. However, in certain situations it may not be the most appropriate model, for example it cannot adequently explain the long memory seen in the data or change according to shifts in the world economy. Therefore, recently attention has been paid to tvARCH models (see, for example, Mikosch and Stărică (2003), Dahlhaus and Subba Rao (2006), Fryzlewicz et al. (2008) and Fryzlewicz and Subba Rao (2008)) and ARCH\((\infty)\) models (see Robinson (1991), Giraitis et al. (2000), Giraitis and Robinson (2001) and Subba Rao (2006)). The derivations of the sampling properties of some of the above mentioned papers rely on quite sophisticated assumptions on the dependence structure, in particular their mixing properties.

We will show that due to the p-Markovian nature of the time-varying ARCH\((p)\) process, the \(\alpha\)-mixing, 2-mixing and \(\beta\)-mixing bound has the same geometric rate. The story is different for ARCH\((\infty)\) processes, where the mixing rates can be different and vary according to the rate of decay of the parameters. An advantage of the approach advocated in this paper is that these methods can readily be used to establish mixing rates of several time series models. This is especially useful in time series analysis, for example, change point detection schemes for nonlinear
time series, where strong mixing of the underlying process is often required. The price we pay for the flexibility of our approach is that the assumptions under which we work are slightly stronger than the standard assumptions required to prove geometric mixing of the stationary GARCH process. However, the conditions do not rely on proving irreducibility (which is usually required when showing geometric ergodicity) of the underlying process, which can be difficult to verify.

In Section 2 we derive a bound for the mixing rate of general stochastic processes, in terms of the differences of conditional densities. In Section 3 we derive mixing bounds for time-varying ARCH(\(p\)) processes (where \(p\) is finite). In Section 4 we derive mixing bounds for ARCH(\(\infty\)) processes. Proofs which are not in the main body of the paper can be found in the appendix.

2 Some mixing inequalities for general processes

2.1 Notation

For \(k > 0\), let \(X_{t-k} = (X_t, \ldots, X_{t-k})\); if \(k \leq 0\), then \(X_{t-k} = 0\). Let \(y_s = (y_s, \ldots, y_0)\). Let \(\| \cdot \|\) denote the \(\ell_1\)-norm. Let \(\Omega\) denote the sample space. The sigma-algebra generated by \(X_t, \ldots, X_{t+r}\) is denoted as \(\mathcal{F}_{t+r} = \sigma(X_t, \ldots, X_{t+r})\).

2.2 Some mixing inequalities

Let us suppose \(\{X_t\}\) is an arbitrary stochastic process. In this section we derive some bounds for \(\alpha(k)\), \(\hat{\alpha}(k)\) and \(\beta(k)\). To do this we will consider bounds for

\[
\sup_{H \subseteq \mathcal{F}_{t-r_1}^l, G \subseteq \mathcal{F}_{t+k+r_2}^{l+k}} |P(G \cap H) - P(G)P(H)| \quad \text{and} \quad \sup_{\{H_j\} \subseteq \mathcal{F}_{t-r_1}^l, \{G_i\} \subseteq \mathcal{F}_{t+k+r_2}^{l+k}} \sum_{i,j} |P(G_i \cap H_j) - P(G_i)P(H_j)|, \tag{2.1}
\]

where \(r_1, r_2 \geq 0\) and \(\{G_i\}\) and \(\{H_j\}\) are partitions of \(\Omega\). In the proposition below, we give a bound for the mixing rate in terms of conditional densities. Similar bounds for linear processes have been derived in Chanda (1974) and Gorodetskii (1977) (see also Davidson (1994), Chapter 14). However, the bounds in Proposition 2.1 apply to any stochastic process, and it is this generality that allows us to use the result in later sections, where we derive mixing rates for ARCH-type processes.

**Proposition 2.1** Let us suppose that the conditional density of \(X_{t+k+r_2}^{l+k}\) given \(X_{t-r_1}^l\) exists and
denote it as $f_{X_{t+k}^{t-1} X_{t}^{t-1}}$. For $\eta = (\eta_0, \ldots, \eta_r) \in (\mathbb{R}^+)^{r+1}$, define the set

$$E = \{ \omega; X_{t-1}^{t-1}(\omega) \in \mathcal{E} \} \quad \text{where} \quad \mathcal{E} = \{ (\nu_0, \ldots, \nu_r); \text{for all } |\nu_j| \leq \eta_j \}. \quad (4)$$

Then for all $r_1, r_2 \geq 0$ and $\eta$ we have

$$\sup_{H \in \mathcal{F}_t^{t-1}, G \in \mathcal{F}_{t+k+r_2}^{t+k+r_2}} |P(G \cap H) - P(G)P(H)| \leq \frac{1}{2} \sup_{x \in \mathcal{E}} \int_{\mathbb{R}^{r_1+1}} \left| f_{X_{t+k}^{t-1} X_{t}^{t-1}}(y|x) - f_{X_{t+k}^{t-1} X_{t}^{t-1}}(y|0) \right| dy + 4P(E^c), \quad (5)$$

and

$$\sup_{\{H_j\} \in \mathcal{F}_t^{t-1}, \{G_j\} \in \mathcal{F}_{t+k+r_2}^{t+k+r_2}} \sum_{i,j} |P(G_i \cap H_j) - P(G_i)P(H_j)| \leq \frac{1}{2} \sup_{x \in \mathcal{E}} \int_{\mathbb{R}^{r_1+1}} \left| f_{X_{t+k}^{t-1} X_{t}^{t-1}}(y|x) - f_{X_{t+k}^{t-1} X_{t}^{t-1}}(y|0) \right| dy + 4P(E^c), \quad (6)$$

where $\{G_i\}$ and $\{H_j\}$ are finite partitions of $\Omega$. $X_{t-1}^{t-1}$. Let $W_{t+k-1}^{t+1}$ be a random vector that is independent of $X_{t-1}^{t-1}$ and $f_{W_{t+k-1}^{t+1}}$ denote the density of $W_{t+k-1}^{t+1}$, then we have

$$\sup_{H \in \mathcal{F}_t^{t-1}, G \in \mathcal{F}_{t+k+r_2}^{t+k+r_2}} |P(G \cap H) - P(G)P(H)| \leq \frac{1}{2} \sum_{s=0}^{r_2} \sup_{x \in \mathcal{E}} \int_{\mathbb{R}^s} \left\{ \sup_{s=1} \int_{\mathbb{R}^s} D_{s,k,t}(y_s|y_{s-1}, w, x) d y_s \right\} d w + 4P(E^c) \quad (7)$$

and

$$\sup_{\{H_j\} \in \mathcal{F}_t^{t-1}, \{G_j\} \in \mathcal{F}_{t+k+r_2}^{t+k+r_2}} \sum_{i,j} |P(G_i \cap H_j) - P(G_i)P(H_j)| \leq \frac{1}{2} \sum_{s=0}^{r_2} \int_{\mathbb{R}^s} \left\{ \sup_{s=1} \int_{\mathbb{R}^s} D_{s,k,t}(y_s|y_{s-1}, w, x) d y_s \right\} d w + 4P(E^c) \quad (8)$$

where $D_{0,k,t}(y_0|y_{-1}, w, x) = |f_{s,k,t}(y_0|w, x) - f_{s,k,t}(y_0|w, 0)|$ and for $s \geq 1$

$$D_{s,k,t}(y_s|y_{s-1}, w, x) = |f_{s,k,t}(y_s|y_{s-1}, w, x) - f_{s,k,t}(y_s|y_{s-1}, w, 0)|, \quad (9)$$

with the conditional density of $X_{t+k}$ given $(W_{t+k-1}^{t+1}, X_{t-1}^{t-1})$ denoted as $f_{0,k,t}$ and the conditional density of $X_{t+k+s}$ given $(X_{t+k+s-1}^{t+k}, W_{t+k-1}^{t+1}, X_{t-1}^{t-1})$, denoted as $f_{s,k,t}$, $x = (x_0, \ldots, x_{r_2})$ and
\[ w = (w_k, \ldots, w_1). \]

PROOF. In Appendix A.1. \qed

Since the above bounds hold for all vectors \( \eta \in (\mathbb{R}^{+})^{r_1+1} \) (note \( \eta \) defines the set \( E \); see (4)), by choosing the \( \eta \) which balances the integral and \( P(E^c) \), we obtain an upper bound for the mixing rate.

The main application of the inequality in (7) is to processes which are ‘driven’ by the innovations (for example, linear and ARCH-type processes). If \( W_{t+k-1}^{t+k+1} \) is the innovation process, often it can be shown that the conditional density of \( X_{t+k+s} \) given \( (X_{t+k+s-1}, W_{t+k-1}^{t+k+1}, X_{t}^{(s)}) \) can be written as a function of the innovation density. Deriving the density of \( X_{t+k+s} \) given \( (X_{t+k+s-1}, W_{t+k-1}^{t+k+1}, X_{t}^{(s)}) \) is not a trivial task, but it is often possible. In the subsequent sections we will apply Proposition 2.1 to obtaining bounds for the mixing rates.

The proof of Proposition 2.1 can be found in the appendix, but we give a flavour of it here. Let

\[ H = \{ \omega; X_{t}^{(s)}(\omega) \in \mathcal{H} \}, \quad G = \{ \omega; X_{t+k+s-1}^{(s)}(\omega) \in \mathcal{G} \}. \tag{10} \]

It is straightforward to show that \( |P(G \cap H) - P(G)P(H)| \leq |P(G \cap H \cap E) - P(G \cap E)P(H)| + 2P(E^c) \). The advantage of this decomposition is that when we restrict \( X_{t}^{(s)} \) to the set \( \mathcal{E} \) (i.e. not large values of \( X_{t}^{(s)} \)), we can obtain a bound for \( |P(G \cap H \cap E) - P(G \cap E)P(H)| \). More precisely, by using the inequality

\[
\inf_{x \in \mathcal{E}} P(G \mid X_{t}^{(s)} = x)P(H \cap E) \leq P(G \cap H \cap E) \leq \sup_{x \in \mathcal{E}} P(G \mid X_{t}^{(s)} = x)P(H \cap E),
\]

we can derive upper and lower bounds for \( P(G \cap H \cap E) - P(G \cap E)P(H) \) which depend only on \( E \) and not \( H \) and \( G \), and thus obtain the bounds in Proposition 2.1.

It is worth mentioning that by using (7) one can establish mixing rates for time-varying linear processes (such as the tvMA(\( \infty \)) process considered in Dahlhaus and Polonik (2006)). Using (7) and similar techniques to those used in Section 4, mixing bounds can be obtained for the tvMA(\( \infty \)) process.

In the following sections we will derive the mixing rates for ARCH-type processes, where one of the challenging aspects of the proof is establishing a bound for the integral difference in (9).
3 Mixing for the time-varying ARCH\((p)\) process

3.1 The tvARCH process

In Fryzlewicz et al. (2008) we show that the tvARCH process can be used to explain the commonly observed stylised facts in financial time series (such as the empirical long memory). A sequence of random variables \(\{X_t\}\) is said to come from a time-varying ARCH\((p)\) if it satisfies the representation

\[
X_t = Z_t \left( a_0(t) + \sum_{j=1}^{p} a_j(t) X_{t-j} \right),
\]

where \(\{Z_t\}\) are independent, identically distributed (iid) positive random variables, with \(\mathbb{E}(Z_t) = 1\) and \(a_j(\cdot)\) are positive parameters. It is worth comparing (11) with the tvARCH process used in the statistical literature. Unlike the tvARCH process considered in, for example, Dahlhaus and Subba Rao (2006) and Fryzlewicz et al. (2008), we have not placed any smoothness conditions on the time varying parameters \(\{a_j(\cdot)\}\). The smoothness conditions assumed in Dahlhaus and Subba Rao (2006) and Fryzlewicz et al. (2008) are used in order to do parameter estimation. However, in this paper we are dealing with mixing of the process, which does not require such strong assumptions. The assumptions that we require are stated below.

**Assumption 3.1**

(i) For some \(\delta > 0\), \(\sup_{t \in \mathbb{Z}} \sum_{j=1}^{p} a_j(t) \leq 1 - \delta\).

(ii) \(\inf_{t \in \mathbb{Z}} a_0(t) > 0\) and \(\sup_{t \in \mathbb{Z}} a_0(t) < \infty\).

(iii) Let \(f_Z\) denote the density of \(Z_t\). For all \(a > 0\) we have \(\int |f_Z(u) - f_Z(u[1+a])| \, du \leq K a\), for some finite \(K\) independent of \(a\).

(iv) Let \(f_Z\) denote the density of \(Z_t\). For all \(a > 0\) we have \(\int \sup_{0 \leq \tau \leq a} |f_Z(u) - f_Z(u[1+\tau])| \, du \leq K a\), for some finite \(K\) independent of \(a\).

We note that Assumption 3.1(i,ii) guarantees that the ARCH process has a Volterra expansion as a solution (see Dahlhaus and Subba Rao (2006), Section 5). Assumption 3.1(iii,iv) is a type of Lipschitz condition on the density function and is satisfied by various well known distributions, including the chi-squared distributions. We now consider a class of densities which satisfy Assumption 3.1(iii,iv). Suppose \(f_Z : \mathbb{R} \to \mathbb{R}\) is a density function, whose first derivative is
bounded, after some finite point \( m \), the derivative \( f' \) declines monotonically to zero and satisfies \( \int |y f'_Z(y)| dy < \infty \). In this case

\[
\int_0^\infty \sup_{0 \leq \tau \leq a} |f_Z(u) - f_Z(u[1 + \tau])| du \\
\leq \int_0^m \sup_{0 \leq \tau \leq a} |f_Z(u) - f_Z(u[1 + \tau])| du + \int_m^\infty \sup_{0 \leq \tau \leq a} |f_Z(u) - f_Z(u[1 + \tau])| du \\
\leq a \left( m^2 \sup_{u \in \mathbb{R}} |f'_Z(u)| + \int_m^\infty u |f'_Z(u)| du \right) \leq Ka,
\]

for some finite \( K \) independent of \( a \), hence Assumption 3.1(iii,iv) is satisfied.

We use Assumption 3.1(i,ii,iii) to obtain the strong mixing rate (2-mixing and \( \alpha \)-mixing) of the \( \text{tvARCH}(p) \) process and the slightly stronger conditions Assumption 3.1(i,ii,iv) to obtain the \( \beta \)-mixing rate of the \( \text{tvARCH}(p) \) process. We mention that in the case that \( \{X_t\} \) is a stationary, ergodic time series, Francq and Zakoïan (2006) have shown geometric ergodicity, which they show implies \( \beta \)-mixing, under the weaker condition that the distribution function of \( \{Z_t\} \) can have some discontinuities.

### 3.2 The \( \text{tvARCH}(p) \) process and the Volterra series expansion

In this section we derive a Volterra series expansion of the \( \text{tvARCH} \) process (see also Giraitis et al. (2000)). These results allow us to apply Proposition 2.1 to the \( \text{tvARCH} \) process. We first note that the innovations \( Z_{t+k}^{t+1} \) and \( X_{t-k}^{t-p+1} \) are independent random vectors. Hence comparing with Proposition 2.1, we are interested in obtaining the conditional density of \( X_{t+k} \) given \( Z_{t+k}^{t+1} \) and \( X_{t-k}^{t-p+1} \), (denoted \( f_{0,k,t} \)) and the conditional density of \( X_{t+k+s} \) given \( X_{t+k+s-1}^{t+k}, Z_{t+k}^{t+1} \) and \( X_{t-k}^{t-p+1} \) (denoted \( f_{s,k,t} \)). We use these expressions to obtain a bound for \( D_{s,k,t} \) (defined in (9)), which we use to derive a bound for the mixing rate. We now represent \( \{X_t\} \) in terms of \( \{Z_t\} \).

To do this we define

\[
A_t(z) = \begin{pmatrix}
    a_1(t) z_t & a_2(t) z_t & \ldots & a_p(t) z_t \\
    1 & 0 & \ldots & 0 \\
    0 & 1 & \ldots & 0 \\
    \vdots & \vdots & \ddots & \vdots \\
    0 & 0 & 1 & 0
\end{pmatrix}, \quad A_t = A_t(1) = \begin{pmatrix}
    a_1(t) & a_2(t) & \ldots & a_p(t) \\
    1 & 0 & \ldots & 0 \\
    0 & 1 & \ldots & 0 \\
    \vdots & \vdots & \ddots & \vdots \\
    0 & 0 & 1 & 0
\end{pmatrix}
\]

\[
b_t(z) = (a_0(t) z_t, 0, \ldots, 0)' \quad \text{and} \quad X_t^{t-p+1} = (X_t, X_{t-1}, \ldots, X_{t-p+1})'.
\]
Using this notation we have the relation $X_{t+k}^{s+k-p+1} = A_{t+k}(Z)X_{t+k-1}^{s+k-p} + b_{t+k}(Z)$. We mention the vector representation of ARCH and GARCH processes has been used in Bougerol and Picard (1992), Basrak et al. (2002) and Straumann and Mikosch (2006) in order to obtain some probabilistic properties for ARCH-type processes. Now iterating the relation $k$ times (to get $X_{t+k}^{s+k-p+1}$ in terms of $X_{t}^{s+p-1}$) we have

$$X_{t+k}^{s+k-p+1} = b_{t+k}(Z) + \sum_{r=0}^{k-2} \left[ \prod_{i=0}^{r-1} A_{t+k-i}(Z)b_{t+k-r-1}(Z) \right] X_{t+k-r}^{s+k-p+1},$$

(13)

where we set $[\prod_{i=0}^{r-1} A_{t+k-i}(Z)] = I_p$ ($I_p$ denotes the $p \times p$ dimensional identity matrix). We use this expansion below.

**Lemma 3.1** Let us suppose that Assumption 3.1(i) is satisfied. Then for $s \geq 0$ we have

$$X_{t+k+s} = Z_{t+k+s} \{ P_{s,k,t}(Z) + Q_{s,k,t}(Z,X) \},$$

(14)

where for $s = 0$ we have

$$P_{0,k,t}(Z) = a_0(t+k) + [A_{t+k} \sum_{i=1}^{n-2} \prod_{i=1}^{r} A_{t+k-i}(Z)b_{t+k-r-1}(Z)]_1$$

$$Q_{0,k,t}(Z,X) = [A_{t+k} \prod_{i=1}^{k-1} A_{t+k-i}(Z)X_{t}^{s+p-1}]_1 \text{ for } n > t,$$

($[\cdot]_1$ denotes the first element of a vector), for $1 \leq s \leq p$

$$P_{s,k,t}(Z) =$$

$$a_0(t+k+s) + \sum_{i=1}^{s-1} a_i(t+k+s)X_{t+k+s-i} + \sum_{i=s}^{p} a_i(t+k+s)Z_{k+s-i} \left\{ a_0(t+k+s-i) + \right.$$ 

$$\left. [A_{t+k+s-i} \sum_{r=1}^{k+s-i} \{ \prod_{d=0}^{r} A_{t+k+s-i-d}(Z)b_{t+k+s-i-r}(Z) \}]_1 \right\},$$

$$Q_{s,k,t}(Z,X) = \left[ \sum_{i=s}^{p} a_i(t+k+s)Z_{k+s-i}A_{t+k+s-i} \left\{ \prod_{d=0}^{k+s-i} A_{t+k+s-i-d}(Z)X_{t}^{s+p-1} \right\} \right]_1,$$

and for $s > p$ we have $P_{s,k,t}(Z) = a_0(t+k+s) + \sum_{i=1}^{p} a_i(t+k+s)X_{t+k+s-i}$ and $Q_{s,k,t}(Z,X) \equiv 0$. We note that $P_{s,k,t}$ and $Q_{s,k,t}$ are positive random variables, and for $s \geq 1$, $P_{s,k,t}$ is a function of $X_{t+k+s-1}^{s+p-1}$ (but this has been suppressed in the notation).
PROOF. In Appendix A.2.

By using (14) we now show that the conditional density of \( X_{t+k+s} \) given \( X_{t+k+s-1}, Z_{t+k-1} \) and \( X_{t-p} \) is a function of the density of \( Z_{t+k+s} \). It is clear from (14) that \( Z_{t+k+s} \) can be expressed as \( Z_{t+k+s} = X_{t+k+s} P_{s,k,t}(z) + Q_{s,k,t}(z; x) \). Therefore, it is straightforward to show that

\[
  f_{s,k,t}(y_s | y_{s-1}, z, x) = \frac{1}{P_{s,k,t}(z) + Q_{s,k,t}(z; x)} f_Z \left( \frac{y_s}{P_{s,k,t}(z) + Q_{s,k,t}(z; x)} \right). \tag{16}
\]

3.3 Strong mixing of the tvARCH\((p)\) process

The aim in this section is to prove geometric mixing of the tvARCH\((p)\) process without appealing to geometric ergodicity. Naturally, the results in this section also apply to stationary ARCH\((p)\) processes.

In the following lemma we use Proposition 2.1 to obtain bounds for the mixing rates. It is worth mentioning that the techniques used in the proof below can be applied to other Markov processes.

**Lemma 3.2** Suppose \( \{X_t\} \) is a tvARCH process which satisfies (11). Then for any \( \eta = (\eta_0, \ldots, \eta_{p+1}) \in (\mathbb{R}^+)^p \) we have

\[
  \sup_{G \in \mathcal{F}_t^{1+k}, H \in \mathcal{F}_t^{-\infty}} |P(G \cap H) - P(G)P(H)| \\
  \leq 2 \sum_{s=0}^{p-1} \sup_{z \in \mathcal{E}} \int_{\mathbb{R}} \prod_{i=1}^{k-1} f_Z(z_i) \sup_{y_{s-1} \in \mathbb{R}^*} \left\{ \int_{\mathbb{R}} D_{s,k,t}(y_s | y_{s-1}, z, x) dy_s \right\} dz + 4 \sum_{j=0}^{p-1} P(|X_{t-j}| \geq \eta_{j+1}), \tag{17}
\]

and

\[
  \sup_{\{H_i\} \in \mathcal{F}_t^{-\infty}, \{G_i\} \in \mathcal{F}_t^{1+k}} \sum_{i,j} |P(G_i \cap H_j) - P(G_i)P(H_j)| \\
  \leq 2 \sum_{s=0}^{p-1} \sup_{z \in \mathcal{E}} \int_{\mathbb{R}} \prod_{i=1}^{k-1} f_Z(z_i) \sup_{y_{s-1} \in \mathbb{R}^*} \left\{ \int_{\mathbb{R}} D_{s,k,t}(y_s | y_{s-1}, z, x) dy_s \right\} dz + 4 \sum_{j=0}^{p-1} P(|X_{t-j}| \geq \eta_{j+1}), \tag{18}
\]

where \( z = (z_1, \ldots, z_{k-1}) \) and \( \{G_i\} \) and \( \{H_j\} \) are partitions of \( \Omega \).

**PROOF** In Appendix A.2. \qed

To obtain a mixing rate for the tvARCH\((p)\) process we need to bound the integral in (17), then
obtain the set $E$ which minimises (17). We will start by bounding $D_{s,k,t}$, which, we recall, is based on the conditional density $f_{s,k,t}$ (defined in (16)).

**Lemma 3.3** Let $D_{s,k,t}$ and $Q_{s,k,t}$ be defined as in (9) and (15) respectively.

(i) Suppose Assumption 3.1(i,ii,iii) holds, then for all $x \in (\mathbb{R}^p)^p$ we have

$$p - 1 \sum_{s=0}^{p-1} \prod_{i=1}^{k-1} f_Z(z_i) \sup_{y_{s-1} \in \mathbb{R}^p} \left\{ \int D_{s,k,t}(y_s | y_{s-1}, \hat{Z}, \hat{x})dy_s \right\} dz \leq K \frac{E|Q_{s,k,t}(Z, \hat{x})|}{\inf_{t \in \mathbb{Z}} a_0(t)} \leq K (1 - \tilde{\delta})^k \|z\|, \quad (19)$$

where $K$ is a finite constant and $0 < \tilde{\delta} \leq \delta < 1$ ($\delta$ is defined in Assumption 3.1(i)).

(ii) Suppose Assumption 3.1(i,ii,vi) holds, then for any set $E$ (defined as in (4)) we have

$$p - 1 \sum_{s=0}^{p-1} \prod_{i=1}^{k-1} f_Z(z_i) \sup_{y_{s-1} \in \mathbb{R}^p} \left\{ \int \sup_{\hat{Z} \in E} D_{s,k,t}(y_s | y_{s-1}, \hat{Z}, \hat{x})dy_s \right\} dz \leq \sup_{\hat{Z} \in E} K (1 - \tilde{\delta})^k \|z\|. \quad (20)$$

**PROOF.** In Appendix A.2.

We now use the lemmas above to show geometric mixing of the tvARCH process.

**Theorem 3.1** (i) Suppose Assumption 3.1(i,ii,iii) holds, then

$$\sup_{\{G_i\} \in \mathcal{A}(\mathcal{X}^{\alpha+k})} \sup_{H \in \mathcal{A}(\mathcal{X}^{-\alpha})} |P(G \cap H) - P(G)P(H)| \leq K \alpha^k,$$

(ii) Suppose Assumption 3.1(i,ii,iv) holds, then

$$\sup_{\{H_j\} \in \mathcal{A}(\mathcal{X}^{-\alpha})} \sum_{i} \sum_{j} |P(G_i \cap H_j) - P(G_i)P(H_j)| \leq K \alpha^k,$$

for any $\sqrt{1 - \delta} < \alpha < 1$, and where $K$ is a finite constant independent of $t$ and $k$.

**PROOF.** We use (17) to prove the (i). (19) gives a bound for the integral difference in (17), therefore all that remains is to bound the probabilities in (17). To do this we first use Markov’s inequality, to give

$$\sum_{j=0}^{p-1} P(|X_{t-j} | \geq \eta_{-j}) \leq \sum_{j=0}^{p-1} E|X_{t-j}| \eta_{-j}^{-1}.$$ By using the Volterra expansion of $X_t$ (see Dahlhaus and Subba Rao (2006), Section 5) it can be shown that $\sup_{t \in \mathbb{Z}} E|X_t| \leq \cdots$
(sup_{t \in \mathbb{Z}} a_0(t))/\sup_{t \in \mathbb{Z}} (1 - \sum_{j=1}^{p} a_j(t))). Using these bounds and substituting (19) into (17) gives for every \eta \in (\mathbb{R}^+) the bound

\sup_{G \in \sigma(X_{t+k})} |P(G \cap H) - P(G)P(H)| \leq 2 \frac{K(1 - \delta)^k \sum_{j=0}^{p-1} \eta^{-j}}{\inf_{t \in \mathbb{Z}} a_0(t)} + 4K \sum_{j=0}^{p-1} \frac{1}{\eta^{-j}}.

We observe the right hand side of the above is minimised when \eta^{-j} = (1 - \tilde{\delta})^{k/2} (for 0 \leq j \leq (p - 1)), which gives the bound

\sup_{H \in \sigma(X_{t+k})} |P(G \cap H) - P(G)P(H)| \leq K \sqrt{(1 - \delta)^k}.

Since the above is true for any 0 < \tilde{\delta} < \delta, (ii) is true for any \alpha which satisfies \sqrt{1 - \delta} < \alpha < 1, thus giving the result.

To prove (ii) we use an identical argument but use the bound in (20) instead of (19), we omit the details. \qed

Remark 3.1 We observe that K and \alpha defined in the above theorem are independent of t, therefore under Assumption 3.1(i,ii,iii) we have \alpha(k) \leq K \alpha^k (\alpha-mixing, defined in (1)) and under Assumption 3.1(i,ii,iv) \beta(k) \leq K \alpha^k (\beta-mixing, defined in (3)) for all \sqrt{1 - \delta} < \alpha < 1.

Moreover, since \sigma(X_{t+k}) \subset \sigma(X_{t+k}, \ldots, X_{t+p-1}) and \sigma(X_{t}) \subset \sigma(X_{t}, \ldots, X_{t-p+1}) the 2-mixing rate is also geometric with \tilde{\alpha}(k) \leq K \alpha^k (\tilde{\alpha}(k) defined in (2)).

4 Mixing for ARCH(\infty) processes

In this section we derive mixing rates for the ARCH(\infty) process, we first define the process and state the assumptions that we will use.

4.1 The ARCH(\infty) process

The ARCH(\infty) process has many interesting features, which are useful in several applications. For example, under certain conditions on the coefficients, the ARCH(\infty) process can exhibit ‘near long memory’ behaviour (see Giraitis et al. (2000)). The ARCH(\infty) process satisfies the
representation

\[ X_t = Z_t \left( a_0 + \sum_{j=1}^{\infty} a_j X_{t-j} \right), \quad (21) \]

where \( Z_t \) are iid positive random variables with \( \mathbb{E}(Z_t) = 1 \) and \( a_j \) are positive parameters. The GARCH\( (p,q) \) model also has an ARCH\( (\infty) \) representation, where the \( a_j \) decay geometrically with \( j \). Giraitis and Robinson (2001), Robinson and Zaffaroni (2006) and Subba Rao (2006) consider parameter estimation for the ARCH\( (\infty) \) process.

We will use Assumption 3.1 and the assumptions below.

**Assumption 4.1**

(i) We have \( \sum_{j=1}^{\infty} a_j < 1 - \delta \) and \( a_0 > 0 \).

(ii) For some \( \nu > 1 \), \( \mathbb{E}|X_t|^\nu < \infty \) (we note that this is fulfilled if \( \mathbb{E}|Z_t|^\nu \sum_{j=1}^{\infty} a_j < 1 \)).

Giraitis et al. (2000) have shown that under Assumption 4.1(i), the ARCH\( (1) \) process has a stationary solution and a finite mean (that is \( \sup_{t \in \mathbb{Z}} \mathbb{E}(X_t) < \infty \)). It is worth mentioning that since the ARCH\( (1) \) process has a stationary solution the shift \( t \), plays no role when obtaining mixing bounds, ie. \( \sup_{G \in \sigma(X_{k+1}), H \in \sigma(X_t)} |P(G \cap H) - P(G)P(H)| = \sup_{G \in \sigma(X_{k+1}), H \in \sigma(X_0)} |P(G \cap H) - P(G)P(H)| \). Furthermore, the conditional density of \( X_{t+k} \) given \( Z_{t+k-1}^{t+1} \) and \( X_{t-\infty} \) is not a function of \( t \), hence in the section below we let \( f_{0,k} \) denote the conditional density of \( X_{t+k} \) given \( (Z_{t+k-1}^{t+1} \) and \( X_{t-\infty} \) and for \( s \geq 1 \), let \( f_{s,k} \) denote the conditional density of \( X_{t+k+s} \) given \( (X_{t+k+s-1}^{t+k+1}, Z_{t+k-1}^{t+1} \) and \( X_{t-\infty} \)).

### 4.2 The ARCH\( (\infty) \) process and the Volterra series expansion

We now write \( X_k \) in terms of \( Z_{k-1}^{t} \) and \( X = (X_0, X_{-1}, \ldots) \) and use this to derive the conditional densities \( f_{0,k} \) and \( f_{s,k} \). It can be seen from the result below (equation (22)) that in general the ARCH\( (\infty) \) process is not Markovian.

**Lemma 4.1** Suppose \( \{X_t\} \) satisfies (21). Then

\[ X_k = \mathcal{P}_{0,k}(Z)Z_k + \mathcal{Q}_{0,k}(Z, X)Z_k, \quad (22) \]

where
\[ P_{0,k}(Z) = \left[ a_0 + \sum_{m=1}^{k} \sum_{j_m > \ldots > j_1 > 0} \left( \prod_{i=1}^{m-1} a_{j_{i+1} - j_i} \right) \left( \prod_{i=1}^{m-1} Z_{j_i} \right) \right] \]

\[ Q_{0,k}(Z, X) = \sum_{r=1}^{k} \left\{ \sum_{m=1}^{k} \sum_{j_m > \ldots > j_1 > r} \left( \prod_{i=1}^{m-1} a_{j_{i+1} - j_i} \right) \left( \prod_{i=1}^{m-1} Z_{j_i} \right) \right\} d_r(X). \]  

Furthermore, setting \( Q_{0,k} = 0 \), for \( k \geq 1 \) we have that \( Q_{0,k}(Z, X) \) satisfies the recursion \( Q_{0,k}(Z, X) = \sum_{j=1}^{k} a_j Q_{0,k-j}(Z, X) Z_{k-j} + d_k(X) \), where \( d_k(X) = \sum_{j=0}^{\infty} a_{k+j} X_{-j} \) (for \( k \geq 1 \)).

**PROOF.** In Appendix A.3 of the Technical report. \( \square \)

We will use the result above to derive the 2-mixing rate. To derive \( \alpha \) and \( \beta \) mixing we require the density of \( X_{k+s} \) given \( X_{k+s-1}, Z_{k-1}^k \) and \( X_{0}^{-\infty} \), which uses the following lemma.

**Lemma 4.2** Suppose \( \{X_i\} \) satisfies (21). Then for \( s \geq 1 \) we have

\[ X_{k+s} = Z_{k+s} \{ P_{s,k}(Z) + Q_{s,k}(Z, X) \}, \tag{24} \]

where

\[ P_{s,k}(Z) = a_0 + \sum_{j=1}^{s} a_j X_{k+s-j} + \sum_{j=s+1}^{\infty} a_j Z_{k+s-j} P_{0,k+s-j}(Z) \]

\[ Q_{s,k}(Z, X) = \sum_{j=s+1}^{k+s} a_j Z_{k+s-j} Q_{0,k+s-j}(Z, X) + d_{k+s}(X). \tag{25} \]

**PROOF.** In Appendix A.3 of the Technical report.

Using (22) and (24) for all \( s \geq 0 \) we have that \( Z_{k+s} = \frac{X_{k+s}}{P_{s,k}(Z) + Q_{s,k}(Z, X)} \), which leads to the conditional densities

\[ f_{s,k}(y_s | y_{s-1}, z, x) = \frac{1}{P_{s,k}(z) + Q_{s,k}(z, x)} f_z \left( \frac{y_s}{P_{s,k}(z) + Q_{s,k}(z, x)} \right). \tag{26} \]

In the proofs below \( Q_{0,k}(1_{k-1}, z) \) plays a prominent role. By using the recursion in Lemma 4.1 and (25), setting \( x = X_0^{-\infty} \) and noting that \( E(Q_{s,k}(Z, x)) = Q_{s,k}(1_{k-1}, x) \) we obtain the recursion \( Q_{0,k}(1_{k-1}, z) = \sum_{j=1}^{k} a_{j+s} Q_{0,k-j}(1_{k-j-1}, z) + d_{k+s}(x) \). We use this to obtain a solution for \( Q_{0,k}(1_{k-1}, z) \) in terms of \( \{d_k(x)\}_k \) in the lemma below.
Lemma 4.3 Suppose \( \{X_t\} \) satisfies (21) and Assumption 4.1 are fulfilled. Then, there exists \( \{\psi_j\} \) such that for all \( |z| \leq 1 \) we have \((1 - \sum_{j=1}^{\infty} a_j z^j)^{-1} = \sum_{j=0}^{\infty} \psi_j z^j\). Furthermore, if \( \sum_j |j^\alpha a_j| < \infty \), then Hannan and Kavaliers (1986) have shown that \( \sum_j |j^\alpha \psi_j| < \infty \). For \( k \leq 0 \), set \( d_k(\bar{x}) = 0 \) and \( Q_{0,k}(1_{k-1}, \bar{x}) = 0 \), then for \( k \geq 1 \), \( Q_{0,k}(1_{k-1}, \bar{x}) \) has the solution

\[
Q_{0,k}(1_{k-1}, \bar{x}) = \sum_{j=0}^{\infty} \psi_j d_{k-j}(\bar{x}) = \sum_{j=0}^{k-1} \psi_j d_{k-j}(\bar{x}) = \sum_{j=0}^{k-1} \psi_j \left\{ \sum_{i=0}^{\infty} a_{k-j+i} x_i \right\}, \tag{27}
\]

where \( \bar{x} = (x_0, x_{-1}, \ldots) \).

PROOF. In Appendix A.3 of the Technical report. \( \square \)

4.3 Mixing for ARCH(\( \infty \))-type processes

In this section we show that the mixing rates are not necessarily geometric and depend on the rate of decay of the coefficients \( \{a_j\} \) (we illustrate this in the following example). Furthermore for ARCH(\( \infty \)) processes the strong mixing rate and 2-mixing rate can be different.

Example 4.1 Let us consider the ARCH(\( \infty \)) process, \( \{X_t\} \), defined in (21). Giraitis et al. (2000) have shown that if \( a_j \sim j^{-(1+\delta)} \) (for some \( \delta > 0 \)) and \( [E(Z_t^2)]^{1/2} \sum_{j=1}^{\infty} a_j < 1 \), then \( |\text{cov}(X_0, X_k)| \sim k^{-(1+\delta)} \). That is, the absolute sum of the covariances is finite, but ‘only just’ if \( \delta \) is small. If \( Z_t < 1 \), it is straightforward to see that \( X_t \) is a bounded random variable and by using Ibragimov’s inequality (see Hall and Heyde (1980)) we have

\[
|\text{cov}(X_0, X_k)| \leq C \sup_{A \in \sigma(X_0), B \in \sigma(X_k)} |P(A \cap B) - P(A)P(B)|,
\]

for some \( C < \infty \). Noting that \( |\text{cov}(X_0, X_k)| = O(k^{-(1+\delta)}) \) this gives a lower bound of \( O(k^{-(1+\delta)}) \) on the 2-mixing rate. \( \square \)

To obtain the mixing rates we will use Proposition 2.1, this result requires bounds on \( D_{s,k} = |f_{s,k}(y_s|y_{s-1}; \bar{z}, \bar{x}) - f_{s,k}(y_s|y_{s-1}; \bar{z}, 0)| \) and its integral.

Lemma 4.4 Suppose \( \{X_t\} \) satisfies (21), \( f_Z \) is the density of \( Z_t \) and let \( D_{s,k} \) and \( Q_{0,k}(\cdot) \) be
defined as in (9) and (23). Suppose Assumptions 3.1(iii) and 4.1 are fulfilled, then
\[
\int \prod_{i=1}^{k-1} f_Z(z_i) \left\{ \int |f_{0,k}(y|z,x) - f_{0,k}(y|z,0)| \, dy \right\} \, dz \leq \frac{Q_{0,k}(1_{k-1},x)}{a_0} = \sum_{j=0}^{k-1} |\psi_j| \left\{ \sum_{i=0}^{\infty} a_{k-j+i} x_{-i} \right\}
\]  
(28)

and for \( s \geq 1 \)
\[
\int \prod_{i=1}^{k-1} f_Z(z_i) \left\{ \sup_{y_{s-1} \in \mathbb{R}} \int \mathcal{D}_{s,k}(y_{s-1}, z, x) \, dy_s \right\} \, dz \leq \frac{1}{a_0} \left\{ \sum_{j=s+1}^{k+s} \sum_{l=0}^{k+s-j} |\psi_l| \sum_{i=0}^{\infty} a_{k+s-j-l+i} x_{-i} + \sum_{i=0}^{\infty} a_{k+s+i} x_{-i} \right\}
\]
(29)

Suppose Assumptions 3.1(iv) and 4.1 are fulfilled, and \( \mathcal{E} \) is defined as in (4) then
\[
\int \prod_{i=1}^{k-1} f_Z(z_i) \left\{ \sup_{y_{s-1} \in \mathbb{R}} \sup_{z \in \mathcal{E}} \int \mathcal{D}_{s,k}(y_{s-1}, z, x) \, dy_s \right\} \, dz
\leq \frac{1}{a_0} \left\{ \sum_{j=s+1}^{k+s} \sum_{l=0}^{k+s-j} |\psi_l| \sum_{i=0}^{\infty} a_{k+s-j-l+i} \eta_{-i} + \sum_{i=0}^{\infty} a_{k+s+i} \eta_{-i} \right\},
\]
(30)

where \( \underline{x} = (x_0, x_{-1}, \ldots) \) is a positive vector.

PROOF. In Appendix A.3 of the Technical report. \( \square \)

We require the following simple lemma to prove the theorem below.

 Lemma 4.5 Let us suppose that \( \{c_i\}, \{d_i\} \) and \( \{\eta_{-i}\} \) are positive sequences, then
\[
\inf_{\nu} \left\{ \sum_{i=0}^{\infty} (c_i \eta_{-i} + d_i \eta_{-i}^{-\nu}) \right\} = (\nu^{-1/\nu} + \nu^{1-1/\nu}) \sum_{i=0}^{\infty} c_i^{1/\nu} d_i^{1-1/\nu}.
\]
(31)

PROOF. In Appendix A.3 of the Technical report. \( \square \)

In the following theorem we obtain \( \alpha \)-mixing and \( \beta \)-mixing bounds for the ARCH(\( \infty \)) process.

Theorem 4.1 Suppose \( \{X_t\} \) satisfies (21).
(a) Suppose Assumptions 3.1(iii) and 4.1 hold. Then, we have

\[
\sup_{G \in \mathcal{F}_k, H \in \mathcal{F}_0} |P(G \cap H) - P(G)P(H)|
\]

\[
\leq K(\nu) \sum_{i=0}^{\infty} \left[ \frac{1}{a_0} \sum_{s=0}^{\infty} \sum_{j=s+1}^{k+s} a_j \sum_{t=0}^{k+s-j} |\psi| a_k + \frac{1}{a_0} \sum_{s=0}^{\infty} a_k + s \sum_{j=s+1}^{k+s-j} \sum_{l=0}^{k+s-l} |\psi| a_k + l \right] \frac{1}{\nu^{\nu+1}} \cdot \frac{1}{\nu^{\nu+1}} \cdot [E|X_0|^\nu]^{\frac{1}{\nu+1}} \tag{32}
\]

where \( K(\nu) = 3(\nu^{\nu+1} + \nu^{-\nu+1}) \).

(i) If the parameters of the ARCH(\( \infty \)) process satisfy \(|a_j| \sim j^{-\delta} \) and the \(|\psi_j| \sim j^{-\delta} \) (defined in Lemma 4.3), then we have

\[
\sup_{G \in \mathcal{F}_k, H \in \mathcal{F}_0} |P(G \cap H) - P(G)P(H)| \leq K \left( k(k+1)^{-\delta+3} + (k+1)^{-\delta+2} \right),
\]

where \( \tilde{\delta} = \delta \times (\frac{\nu}{\nu+1}) \).

(ii) If the parameters of the ARCH(\( \infty \)) process satisfy \(|a_j| \sim \delta^j \) and \(|\psi_j| \sim \delta^j \), where \( 0 < \delta < 1 \) (an example is the GARCH(p,q) process), then we have

\[
\sup_{G \in \mathcal{F}_k, H \in \mathcal{F}_0} |P(G \cap H) - P(G)P(H)| \leq C \cdot \cdot \cdot
\]

where \( C \) is a finite constant.

(b) Suppose Assumptions 3.1(iv) and 4.1 hold. Then, we have

\[
\sup_{\{G_i\} \in \mathcal{F}_k, \{H_j\} \in \mathcal{F}_0} \sum_{i} \sum_{j} |P(G_i \cap H_j) - P(G_i)P(H_j)|
\]

\[
\leq K(\nu) \sum_{i=0}^{\infty} \left[ \frac{1}{a_0} \sum_{s=0}^{\infty} \sum_{j=s+1}^{k+s} a_j \sum_{t=0}^{k+s-j} |\psi| a_k + \frac{1}{a_0} \sum_{s=0}^{\infty} a_k + s \sum_{j=s+1}^{k+s-j} \sum_{l=0}^{k+s-l} |\psi| a_k + l \right] \frac{1}{\nu^{\nu+1}} \cdot [E|X_0|^\nu]^{\frac{1}{\nu+1}} \tag{33}
\]

where \( \{G_i\} \) and \( \{H_j\} \) are partitions of \( \Omega \). We mention that the bounds for the \( \alpha \)-mixing rates for different orders of \( \{a_j\} \) and \( \{\psi_j\} \) derived in (i) also hold for the \( \beta \)-mixing rate.

**PROOF.** We first prove (a). We use that

\[
\sup_{G \in \mathcal{F}_k, H \in \mathcal{F}_0} |P(G \cap H) - P(G)P(H)| = \lim_{n \to \infty} \sup_{H \in \mathcal{F}_0} |P(G \cap H) - P(G)P(H)|.
\]
and find a bound for each $n$. By using (5) to bound $\sup_{G \in \mathcal{F}_{k,n}, H \in \mathcal{F}_0} |P(G \cap H) - P(G)P(H)|$ we see that for all sets $\mathcal{E}$ (as defined in (4)) we have

$$\sup_{G \in \mathcal{F}_{k,n}, H \in \mathcal{F}_0} |P(G \cap H) - P(G)P(H)|$$

$$\leq 2 \sup_{z \in \mathbb{E}} \frac{n}{2} \int_{\mathbb{R}^k} \prod_{i=1}^{k-1} f(z_i) \sup_{y_{s-1} \in \mathbb{R}^s} \left\{ \int_{\mathbb{R}} D_{s,k}(y_s|y_{s-1}, \bar{z}, \bar{x}) dy_s dy_z \right\} + 4P(X_0 > \eta_0 \text{ or } \ldots \text{ or } X_{-n} > \eta_{-n}).$$

To bound the integral in (34) we use (29) to obtain

$$= \frac{1}{\alpha_0} \left\{ \sum_{j=s+1}^{k+s} a_j \sum_{l=0}^{k+s-j} |\psi_l| \sum_{i=0}^\infty a_{k+s-j-l+i} \eta_{-i} + \sum_{i=0}^\infty a_{k+s+i} \eta_{-i} \right\}. \quad (35)$$

Now by using Markov’s inequality we have that $P(X_0 > \eta_0 \text{ or } \ldots \text{ or } X_{-n} > \eta_{-n}) \leq \sum_{i=0}^{n} \frac{E(|X_s|^p)}{\eta_{-i}^p}$. Substituting (35) and the above into (34) and letting $n \to \infty$ gives

$$\sup_{G \in \mathcal{F}_{k,n}, H \in \mathcal{F}_0} |P(G \cap H) - P(G)P(H)|$$

$$\leq \inf_{\eta} \left[ \frac{2}{\alpha_0} \sum_{s=0}^{\infty} \sum_{j=s+1}^{k+s} \sum_{l=0}^{k+s-j} \sum_{i=0}^\infty |\psi_l| a_{k+s-j-l+i} \eta_{-i} + \sum_{i=0}^\infty a_{k+s+i} \eta_{-i} \right] + 4E|X_0|^p \sum_{i=0}^\infty \eta_{-i}^p \quad (36)$$

where $\eta = (\eta_0, \eta_{-1}, \ldots)$. Now we use (31) to minimise (36), which gives us (33). The proof of (i) can be found in the appendix. It is straightforward to prove (ii) using (31).

The proof of (b) is very similar to the proof of (a) but uses (30) rather than (29), we omit the details. \hfill \Box

**Remark 4.1** Under the assumptions in Theorem 4.1(a) we have a bound for the $\alpha$-mixing rate, that is $\alpha(k) \leq \zeta(k)$, where $\zeta(k) = K \left[ \frac{1}{\alpha_0} \sum_{s=0}^{\infty} \sum_{j=s+1}^{k+s} a_j \sum_{l=0}^{k+s-j} \sum_{i=0}^\infty |\psi_l| a_{k+s-j-l+i} + \frac{1}{\alpha_0} \sum_{s=0}^{\infty} a_{k+s+i} \right]^{\frac{1}{2}}.

Under the assumptions in Theorem 4.1(a) the $\beta$-mixing coefficient is bounded by $\beta(k) \leq \zeta(k)$.

In the following theorem we consider a bound for the 2-mixing rate of an ARCH($\infty$) process.

**Theorem 4.2** Suppose $\{X_t\}$ satisfies (21) and Assumptions 3.1(iii) and 4.1 holds. Then we
have

\[
\sup_{G \in \sigma(X_k), H \in \mathcal{F}_0^{-\infty}} |P(G \cap H) - P(G)P(H)| \leq K(\nu) \sum_{i=0}^{\infty} \left[ \frac{1}{a_0} \sum_{j=0}^{k-1} a_j |\psi_j| a_{k-j+1} \right]^{\frac{1}{r+\nu}} \left[ \mathbb{E}|X_0|^r \right]^{\frac{1}{r+\nu}}
\]  

(37)

where \( K(\nu) = 3(\nu^{\frac{1}{r+\nu}} + \nu^{-\frac{r}{r+\nu}}) \).

If the parameters of the ARCH(\( \infty \)) process satisfy \( a_j \sim j^{-\delta} \) and \( |\psi_j| \sim j^{-\delta} \) (\( \psi_j \) defined in Lemma 4.3), then we have

\[
\sup_{G \in \sigma(X_k), H \in \mathcal{F}_0^{-\infty}} |P(G \cap H) - P(G)P(H)| \leq K \cdot k(k+1)^{-\tilde{\delta}+1}
\]

(38)

where \( \tilde{\delta} = \delta \times \left( \frac{\nu}{\nu+1} \right) \).

PROOF. We use a similar proof to the proof of Theorem 4.1. The integral difference is replaced with the bound in (28) and again we use Markov's inequality, together they give the bound

\[
\sup_{G \in \sigma(X_k), H \in \mathcal{F}_0^{-\infty}} |P(G \cap H) - P(G)P(H)| \leq \inf_{\nu} \left[ 2 \frac{1}{a_0} \sum_{j=0}^{k-1} |\psi_j| \left( \sum_{i=0}^{\infty} a_{k-j+i} \eta_{-i} \right) + 4\mathbb{E}|X_0|^r \sum_{i=0}^{\infty} \eta_{-i}^{r} \right].
\]

(39)

Finally to obtain (37) and (38) we use (39) and a proof similar to Theorem 4.1(i) hence we omit the details.

Remark 4.2 Comparing (38) and Theorem 4.1(i) we see that the 2-mixing bound is of a smaller order than the strong mixing bound.

In fact, it could well be that the 2-mixing bound is of a smaller order than Theorem 4.2(i). This is because Theorem 4.2(i) gives a bound for \( \sup_{G \in \sigma(X_k), H \in \sigma(X_0,X_{-1},\ldots)} |P(G \cap H) - P(G)P(H)| \) whereas the 2-mixing bound restricts the sigma-algebra of the left tail to \( \sigma(X_0) \). However, we have not been able to show this and this is a problem that requires further consideration.

Acknowledgments

We would like to thank Piotr Kokoszka, Mika Meitz and Joseph Tadjuidje for several useful discussions. We also thank the Associate Editor and two anonymous referees for suggestions and comments which greatly improved many aspects of the paper. A Proofs

A.1 Proof of Proposition 2.1

We will use the following three lemmas to prove Proposition 2.1.

**Lemma A.1** Let $G \in \mathcal{F}^{t+k}_{t+k+r_2} = \sigma(X^{t+k}_{t+k+r_2})$ and $H, E \in \mathcal{F}^t_t = \sigma(X^t_t)$ (where $E$ is defined in (4)), and use the notation in Proposition 2.1. Then we have

\begin{equation}
|P(G \cap H \cap E) - P(G \cap E)P(H)| \leq 2P(H) \sup_{x \in \bar{E}} \left| P(G|X^t_t = x) - P(G|X^t_t = 0) \right| + \inf_{x \in \bar{E}} P(G|X^t_t = x) \left( P(H)P(E^c) + P(H \cap E^c) \right)
\end{equation}

PROOF. To prove the result we first observe that

\[
P(G \cap H \cap E) = P(X^{t+k}_{t+k+r_2} \in \mathcal{G}, X^t_t \in (\mathcal{H} \cap \mathcal{E})) = \int_{\mathcal{H} \cap \mathcal{E}} \int \mathcal{G} dP(X^t_t \leq y, X^{t+k}_{t+k+r_2} \leq x)
\]

\[
= \int_{\mathcal{H} \cap \mathcal{E}} \left\{ \int_{\mathcal{G}} dP(X^{t+k}_{t+k+r_2} \leq y|X^t_t = x) \right\} dP(X^t_t \leq x)
\]

\[
= \int_{\mathcal{H} \cap \mathcal{E}} P(X^{t+k}_{t+k+r_2} \in \mathcal{G}|X^t_t = x) dP(X^t_t \leq x).
\]

Therefore, by using the above and that $P(H \cap E) \leq P(H)$ we obtain the following inequalities

\[
\inf_{x \in \bar{E}} P(X^{t+k}_{t+k+r_2} \in \mathcal{G}|X^t_t = x) P(H \cap E) \leq P(G \cap H \cap E) \leq \sup_{x \in \bar{E}} P(X^{t+k}_{t+k+r_2} \in \mathcal{G}|X^t_t = x) P(H) \quad (42)
\]

\[
\inf_{x \in \bar{E}} P(X^{t+k}_{t+k+r_2} \in \mathcal{G}|X^t_t = x) P(E) \leq P(G \cap E) \leq \sup_{x \in \bar{E}} P(X^{t+k}_{t+k+r_2} \in \mathcal{G}|X^t_t = x) P(E). \quad (43)
\]

Subtracting (42) from (43) and using $P(H \cap E) = P(H) - P(H \cap E^c)$ give the inequalities

\[
P(G \cap H \cap E) - P(G \cap E)P(H) \leq \sup_{x \in \bar{E}} P(X^{t+k}_{t+k+r_2} \in \mathcal{G}|X^t_t = x) P(H) - \inf_{x \in \bar{E}} P(X^{t+k}_{t+k+r_2} \in \mathcal{G}|X^t_t = x) P(H) + P(E^c)P(H) \quad (44)
\]

\[
P(G \cap H \cap E) - P(G \cap E)P(H) \geq \inf_{x \in \bar{E}} P(X^{t+k}_{t+k+r_2} \in \mathcal{G}|X^t_t = x) P(H) - \sup_{x \in \bar{E}} P(X^{t+k}_{t+k+r_2} \in \mathcal{G}|X^t_t = x) P(H) - P(E^c \cap H). \quad (45)
\]
Combining (44) and (45) we obtain

\[ |P(G \cap H \cap E) - P(G \cap E)P(H)| \]

\[ \leq P(H) \sup_{x \in \mathcal{E}} P(G|X_{t-r_1}^t = x) - \inf_{x \in \mathcal{E}} P(G|X_{t-r_1}^t = x) + \inf_{x \in \mathcal{E}} P(G|X_{t-r_1}^t = x) \left\{ P(H)P(E^c) + P(H \cap E^c) \right\} \]

Using the triangle inequality we have

\[ \left| \sup_{x \in \mathcal{E}} P(G|X_{t-r_1}^t = x) - \inf_{x \in \mathcal{E}} P(G|X_{t-r_1}^t = x) \right| \leq 2 \sup_{x \in \mathcal{E}} \left| P(G|X_{t-r_1}^t = x) - P(G|X_{t-r_1}^t = 0) \right| . \]

Substituting the above into (46) gives (40), as required.

We now obtain a bound for the first term on the right hand side of (40).

**Lemma A.2** Let \( f_{X_{t+k}^t|X_{t-r_1}^t} \) denote the density of \( X_{t+k+1}^t \) given \( X_{t-r_1}^t \) and \( \mathcal{G} \) and \( \mathcal{H} \) be defined as in (10), then

\[ |P(G|X_{t-r_1}^t = x) - P(G|X_{t-r_1}^t = 0)| \leq \int_{\mathcal{G}} D_{0,k,t}(y|x)dy. \]  

(47)

Let \( W_{t+k-1} \) be a random vector which is independent of \( X_{t-r_1}^t \) and let \( f_W \) denote the density of \( W_{t+k-1} \). If \( G \in \sigma(X_{t+k}) \) then

\[ \int_{\mathcal{G}} |f_{X_{t+k}^t|X_{t-r_1}^t}(y|x) - f_{X_{t+k}^t|X_{t-r_1}^t}(y|0)| dy \leq \int_{\mathbb{R}^{k-1}} f_W(w) \left\{ \int_{\mathcal{G}} D_{0,k,t}(y|x) dy \right\} dw \]  

(48)

and if \( G \in \sigma(X_{t+k+1}^t) \) then

\[ \int_{\mathcal{G}} |f_{X_{t+k+1}^t|X_{t-r_1}^t}(y|x) - f_{X_{t+k+1}^t|X_{t-r_1}^t}(y|0)| dy \leq \sum_{s=0}^{r_2} \int_{\mathbb{R}^{k-1}} f_W(w) \left\{ \sup_{y_{s-1}} \int_{\mathcal{G}_s} D_{s,k,t}(y_s|y_{s-1},w,x) dy_s \right\} dw, \]

(49)

where \( \mathcal{G} = \mathcal{G}_1 \otimes \ldots \otimes \mathcal{G}_n, \) and \( \mathcal{G}_j \subset \mathbb{R} \).

**PROOF.** The proof of (47) is clear, hence we omit the details.

To prove (48) we first note that by independence of \( W_{t+k-1} \) and \( X_{t-r_2}^t \) we have that \( f_{W|X_{t-r_1}^t}(w|x) = f_W(w) \), where \( f_{W|X_{t-r_1}^t} \) is the conditional density of \( W_{t+k-1} \) given \( X_{t-r_1}^t \). Therefore we have

\[ f_{X_{t+k}^t|X_{t-r_1}^t}(y|x) = \int_{\mathbb{R}^{k-1}} f_{X_{t+k}^t|W,X_{t-r_1}^t}(y|w,x) f_W(w) dw = \int_{\mathbb{R}^{k-1}} f_{0,k,t}(y|w,x) f_W(w) dw. \]
Now substituting the above into \( \int_{\mathcal{G}} |f_{X_{t+k+2}^{\text{c}}}^{X_{t-1}^{\text{c}}}(y|x) - f_{X_{t+k}^{\text{c}}}^{X_{t-1}^{\text{c}}}(y|0)| \, dy \) gives (48).

To prove (49) we note by using the same argument to prove (48) we have

\[
 f_{X_{t+k+2}^{\text{c}}}^{X_{t-1}^{\text{c}}}(y|x) = \int_{\mathbb{R}^{k-1}} f_w(w) \prod_{s=0}^{r_2} f_{s,k,t}(y_s|y_{s-1}, w, x) \, dw. \tag{50}
\]

Now repeatedly subtracting and adding \( f_{s,k,t} \) from the above gives

\[
 f_{X_{t+k+2}^{\text{c}}}^{X_{t-1}^{\text{c}}}(y|x) - f_{X_{t+k}^{\text{c}}}^{X_{t-1}^{\text{c}}}(y|0) = \sum_{s=0}^{r_2} \int_{\mathbb{R}^{k-1}} f_w(w) \left\{ \prod_{a=0}^{s-1} f_{a,k,t}(y_a|y_{a-1}, w, x) \right\} \times \sum_{b=s+1}^{r_2} \int_{\mathcal{G}_b} f_{b,k,t}(y_b|y_{b-1}, w, x) \, dy_b \right\} \times \sup_{y_{s-1}} \int_{\mathcal{G}_s} |f_{s,k,t}(y_s|y_{s-1}, w, x) - f_{s,k,t}(y_s|y_{s-1}, w, 0)| \, dy_s \, dw. \tag{51}
\]

Therefore taking the integral of the above over \( \mathcal{G} \) gives

\[
 \int_{\mathcal{G}} |f_{X_{t+k+2}^{\text{c}}}^{X_{t-1}^{\text{c}}}(y|x) - f_{X_{t+k}^{\text{c}}}^{X_{t-1}^{\text{c}}}(y|0)| \, dy \leq \sum_{s=0}^{r_2} \int_{\mathbb{R}^{k-1}} f_w(w) \left\{ \prod_{a=0}^{s-1} f_{a,k,t}(y_a|y_{a-1}, w, x) \right\} \times \sum_{b=s+1}^{r_2} \int_{\mathcal{G}_b} f_{b,k,t}(y_b|y_{b-1}, w, x) \, dy_b \right\} \times \sup_{y_{s-1}} \int_{\mathcal{G}_s} |f_{s,k,t}(y_s|y_{s-1}, w, x) - f_{s,k,t}(y_s|y_{s-1}, w, 0)| \, dy_s \, dw. \tag{52}
\]

To obtain (49) we observe that since \( \mathcal{G}_j \subset \mathbb{R} \) and \( \int_{\mathbb{R}} f_{s,k,t}(y_s|y_{s-1}, w, x) \, dy_s = 1 \) we have

\[
 (\prod_{a=0}^{s-1} f_{a,k,t}(y_a|y_{a-1}, w, x) \, dy_a) \left( \prod_{b=s+1}^{r_2} \int_{\mathcal{G}_b} f_{b,k,t}(y_b|y_{b-1}, w, x) \, dy_b \right) \leq 1.
\]

Finally substituting the above upper bound into (52) gives (49). □

The following lemma will be used to show \( \beta \)-mixing and uses the above lemmas.

**Lemma A.3** Suppose that \( \{G_i\} \in \mathcal{F}_{t+k+r+2}^{t+k} \), \( \{H_j\} \in \mathcal{F}_{t}^{t-1} \) and \( \{G_i\} \) and \( \{H_j\} \) are partitions of \( \Omega \). Then we have

\[
 \sum_{i,j} |P(G_i \cap H_j \cap E) - P(G_i \cap E)P(H_j)| \\
 \leq 2 \sum_{i} \sup_{x \in \mathcal{E}} |P(G_i | X_{t-1}^{t-r}) = x) - P(G_i | X_{t}^{t-r} = 0)| + 2P(E^c)
\]

and

\[
 \sum_{i,j} |P(G_i \cap H_j \cap E^c) - P(G_i \cap E^c)P(H_j)| \leq 2P(E^c). \tag{53}
\]
PROOF. Substituting the inequality in (40) into \( \sum_{i,j} |P(G_i \cap H_j \cap E) - P(G_i \cap E)P(H_j)| \) gives

\[
\sum_{i,j} |P(G_i \cap H_j \cap E) - P(G_i \cap E)P(H_j)| = 2 \sum_{j} P(H_j) \left( \sup_{i \in \mathcal{E}} |P(G_i|X_i^{t-r}) - P(G_i|X_i^{t-r} = 0)| + \inf_{i \in \mathcal{E}} P(G_i|X_i^{t-r} = \emptyset) \{ P(H_j)P(E^c) + P(H_j \cap E^c) \} \right).
\]

Using the above three lemmas we can now prove Proposition 2.1.

\[\text{PROOF of Proposition 2.1 equation (5)}\]

It is straightforward to show that

\[
|P(G \cap H) - P(G)P(H)| \leq |P(G \cap H \cap E) - P(G \cap E)P(H)| + |P(G \cap H \cap E^c) - P(G \cap E^c)P(H)|.
\]

Now by substituting (47) into Lemma A.1 and using the above gives

\[
|P(G \cap H) - P(G)P(H)| \leq 2 \sup_{\mathcal{E}} \int_{\mathcal{G}} f_{X_i^{t+k+2} | X_i^{t-r} (y|x)} - f_{X_i^{t+k+2} | X_i^{t-r} (y|0)} \, dy + \inf_{\mathcal{E}} P(G|X_i^{t-r} = \emptyset) \{ P(H)P(E^c) + P(H \cap E^c) \} + P(G \cap H \cap E^c) + P(G \cap E^c)P(H).
\]

Finally by using that \( \mathcal{G} \subset \mathbb{R}^{r+1} \), \( P(G \cap H \cap E^c) \leq P(E^c) \), \( P(G \cap E^c)P(H) \leq P(E^c) \) and \( \inf_{\mathcal{E}} P(G|X_i^{t-r} = \emptyset) \leq 1 \) we obtain (5).

\[\text{PROOF of Proposition 2.1 equation (6)}\]

It is worth noting that the proof of (6) is similar to the proof of (5). Using (53) and the same arguments as in the proof of (5) we have

\[
\sum_{i,j} |P(G_i \cap H_j) - P(G_i)P(H_j)| \leq 2 \sum_{i} \sup_{\mathcal{E}} \int_{\mathcal{G}_i} f_{X_i^{t+k+2} | X_i^{t-r} (y|x)} - f_{X_i^{t+k+2} | X_i^{t-r} (y|0)} \, dy + 4P(E^c)
\]

\[
\leq 2 \int_{\mathbb{R}^{r+1}} \sup_{\mathcal{E}} \left| f_{X_i^{t+k+2} | X_i^{t-r} (y|x)} - f_{X_i^{t+k+2} | X_i^{t-r} (y|0)} \right| \, dy + 4P(E^c)
\]

\[
\leq 2 \int_{\mathbb{R}^{r+1}} \sup_{\mathcal{E}} \left| f_{X_i^{t+k+2} | X_i^{t-r} (y|x)} - f_{X_i^{t+k+2} | X_i^{t-r} (y|0)} \right| \, dy + 4P(E^c),
\]

where \( H_j = \{ \omega; X_i^{t-r} (\omega) \in H_j \} \) and \( G_i = \{ \omega; X_i^{t+k+2} (\omega) \in G_i \} \), which gives (6).
PROOF of Proposition 2.1 equation (7). To prove (7) we note that \( \int G_s D_{s,k,t}(y_s|y_{s-1}, w, z)dy_s \leq \int R D_{s,k,t}(y_s|y_{s-1}, w, z)dy_s \). Now by substituting this inequality into (49) and what results into (5) gives (7). \( \square \)

PROOF of Proposition 2.1 equation (8). To prove (8) we use (49) and that for all positive functions \( f, \sum_i \int G_s, f(u)du \leq \int R f(u)du \) we have

\[
\sum_i \int \sup_{G_s, z \in \mathcal{E}} |f_{X_t+k}^{t+k+r_2}|X_t-r_1(y, z)| - f_{R}^{t+k+r_2} X_t-r_1(y, 0)|dy \\
\leq \sum_i \sum_{s=0}^{r_2} \int \mathbb{R}^k f_W(w) \sup_{y_{s-1} \in (R^+)^*} \left\{ \int \sup_{y_{s-1}, z \in \mathcal{E}} D_{s,k,t}(y_s|y_{s-1}, w, z)dy_s \right\}dw \\
\leq \sum_{s=0}^{r_2} \int \mathbb{R}^k f_W(w) \sup_{y_{s-1} \in (R^+)^*} \left\{ \int \sup_{y_{s-1}, z \in \mathcal{E}} D_{s,k,t}(y_s|y_{s-1}, w, z)dy_s \right\}dw
\]

where \( G_s = G_{s,1} \otimes \ldots \otimes G_{s,n} \) and \( G_{s,i} \subset \mathbb{R} \). Finally substituting the above into the right hand side of (6) gives (8). \( \square \)

### A.2 Proofs in Section 3

PROOF of Lemma 3.2 We first note that since \( \{X_t\} \) satisfies a tvARCH(\( p \)) representation \((p < \infty)\) it is \( p \)-Markovian, hence for any \( r_2 > p \) the sigma-algebras generated by \( X_t+k \) and \( Z_t+k+p \) are the same. Moreover, by using that for all \( \tau > t, Z_\tau \) is independent of \( X_\tau \) we have

\[
\sup_{G \in \mathcal{F}_{t+k}^\infty, H \in \mathcal{F}_{t}^{-\infty}} |P(G \cap H) - P(G)P(H)| = \sup_{G \in \mathcal{F}_{t+k+p-1}^\infty, H \in \mathcal{F}_{t}^{-p+1}} |P(G \cap H) - P(G)P(H)|. \tag{56}
\]

Now by using the above, Proposition 2.1, equation (7), and that \( Z_{t+k-1}^{t+1} \) and \( X_t^{t-p+1} \) are independent, for any set \( \mathcal{E} \) (defined as in (4)) we have

\[
\sup_{G \in \mathcal{F}_{t+k+p-1}^\infty, H \in \mathcal{F}_{t}^{-p+1}} |P(G \cap H) - P(G)P(H)| \\
\leq 2 \sup_{z \in \mathcal{E}} \sum_{s=0}^{p-1} \prod_{i=1}^{k-1} f_Z(z_i) \sup_{y_{s-1} \in \mathbb{R}^k} \left\{ \int D_{s,k,t}(y_s|y_{s-1}, z, x)dy_s \right\}dz + 4P(X_t > \eta_0) \text{ or } \ldots X_{t-p+1} > \eta_{p+1}) \tag{57}
\]
Finally using that $P(X_t > \eta_0 \text{ or } X_{t-1} > \eta_1 \ldots X_{t-p+1} > \eta_{p-1}) \leq \sum_{j=0}^{p-1} P(X_{t-j} > \eta_j)$ gives (17).

The proof of (18) uses a similar proof as that given above, but uses (8) instead of (7), we omit the details. □

**PROOF of Lemma 3.1** We first prove (14) with $s = 0$. Suppose $k \geq 1$ and focusing on the first element of $X_{t+k}^{t+p-1}$ in (13) and factoring out $Z_{t+k}$ gives

$$X_{t+k} = Z_{t+k} \{ a_0(t + k) + [A_{t+k} \prod_{i=1}^{k-2} A_{t+k-i}(Z)b_{t+k-r-1}(Z)]_1 + [A_{t+k} \prod_{i=1}^{k-1} A_{t+k-i}(Z)X_{t+p-1}^{t+p-1}]_1 \},$$

which is (14) (with $s = 0$). To prove (14) for $1 \leq s \leq p$, we notice by using the tvARCH($p$) representation in (11) and (14) for $s = 0$ gives

$$X_{t+k+s} = Z_{t+k+s} \left\{ a_0(t + k + s) + \sum_{i=1}^{s-1} a_i(t + k + s)X_{t+k+s-i} + \sum_{i=s}^{p} a_i(t + k + s)X_{t+k+s-i} \right\}$$

$$= Z_{t+k+s} \{ P_{s,k,t}(Z) + Q_{s,k,t}(Z, X) \},$$

where $P_{s,k,t}$ and $Q_{s,k,t}$ are defined in (15). Hence this gives (14). Since $a_j(\cdot)$ and $Z_t$ are positive, it is clear that $P_{s,k,t}$ and $Q_{s,k,t}$ are positive random variables. □

We require the following simple lemma to prove Lemmas 3.3 and 4.4.

**Lemma A.4** Suppose that Assumption 3.1(iii) is satisfied, then for any positive $A$ and $B$ we have

$$\int_\mathbb{R} \left| \frac{1}{A+B} f_Z\left(\frac{y}{A+B}\right) - \frac{1}{A} f_Z\left(\frac{y}{A}\right) \right| dy \leq K\left(\frac{B}{A} + \frac{B}{A+B}\right).$$

Suppose that Assumption 3.1(iv) is satisfied, then for any positive $A$, positive continuous function $B : \mathbb{R}^{r+1} \rightarrow \mathbb{R}$ and set $E$ (defined as in (4)) we have

$$\int_{\mathbb{R}} \sup_{z \in E} \left| \frac{1}{A+B(z)} f_Z\left(\frac{y}{A+B(z)}\right) - \frac{1}{A} f_Z\left(\frac{y}{A}\right) \right| dy \leq K \sup_{z \in E} \frac{B(z)}{A} + \frac{B(z)}{A+B(z)}.$$  \hspace{1cm} (59)

**PROOF.** To prove (58) we observe that

$$\int_\mathbb{R} \left| \frac{1}{A+B} f_Z\left(\frac{y}{A+B}\right) - \frac{1}{A} f_Z\left(\frac{y}{A}\right) \right| dy = I + II$$

25
where \( I = \int_{\mathbb{R}} \frac{1}{A+B} |f_Z(y) - f_Z(y)\frac{y}{A+B}|dy \) and \( II = \int_{\mathbb{R}} \left( \frac{1}{A+B} - \frac{1}{A} \right) f_Z(y) \frac{y}{A} dy \).

To bound \( I \), we note that by changing variables with \( u = y/(A+B) \) and under Assumption 3.1(iii) we get

\[
I \leq \int_{\mathbb{R}} |f_Z(u) - f_Z(u(1 + \frac{B}{A}))|du \leq K \frac{B}{A}.
\]

It is straightforward to show \( II \leq \frac{B}{A+B} \). Hence the bounds for \( I \) and \( II \) give (58).

The proof of (59) is the same as above, but uses Assumption 3.1(iv) instead of Assumption 3.1(iii), we omit the details. \( \square \)

**PROOF of Lemma 3.3.** We first show that

\[
\sup_{y_{s-1} \in \mathbb{R}^s} \int_{\mathbb{R}} D_{s,k,t}(y_s y_{s-1}, z, \bar{x}) dy_s \leq \frac{K}{\inf_{t \in \mathbb{Z}} a_0(t)} Q_{s,k,t}(z, \bar{x})
\]

and use this to prove (19). We note that when \( z = 0 \), \( Q_{s,k,t}(z, 0) = 0 \) and \( f_{s,k,t}(y_s| y_{s-1}, z, 0) = P_{s,k,t}(z)^{-1} f_Z(y_s| \frac{y_s}{P_{t+k+s+t+k}(z)}) \). Therefore using (16) gives

\[
D_{s,k,t}(y_s| y_{s-1}, z, \bar{x}) = \left| \frac{1}{P_{s,k,t}(z) + Q_{s,k,t}(z, \bar{x})} f_Z(y_s| \frac{y_s}{P_{s,k,t}(z) + Q_{s,k,t}(z, \bar{x})}) - \frac{1}{P_{s,t+k}(z)} f_Z(y_s| \frac{y_s}{P_{s,t+k}(z)}) \right|.
\]

Now recalling that \( P_{s,k,t} \) and \( Q_{s,k,t} \) are both positive and setting \( A = P_{s,k,t}(z) \) and \( B = Q_{s,k,t}(z, \bar{x}) \) and using (58) we have

\[
\int_{\mathbb{R}} D_{s,k,t}(y_s| y_{s-1}, z, \bar{x}) dy_s \leq K \left( \frac{Q_{s,k,t}(z, \bar{x})}{P_{s,k,t}(z)} + \frac{Q_{s,k,t}(z, \bar{x})}{P_{s,t+k}(z) + Q_{s,k,t}(z, \bar{x})} \right).
\]

Finally, since \( P_{s,k,t}(z) > \inf_{t \in \mathbb{Z}} a_0(t) \) we have \( \int_{\mathbb{R}} D_{s,k,t}(y_s| y_{s-1}, z, \bar{x}) dy_s \leq K Q_{s,k,t}(z, \bar{x}) / \inf_{t \in \mathbb{Z}} a_0(t) \), thus giving (60). By using (60) we now prove (19). Substituting (60) into the integral on the left hand side of (19) and using that \( \mathbb{E}[Q_{s,k,t}(z, \bar{x})] = Q_{s,k,t}(1_{k-1}, \bar{x}) \), using this and substituting (60) into (17) gives

\[
\int \prod_{i=1}^{k-1} f_Z(z_i) \sup_{y_{s-1} \in \mathbb{R}^s} \left\{ \int_{\mathbb{R}} D_{s,k,t}(y_s| y_{s-1}, z, \bar{x}) dy_s \right\} dz \leq K \frac{\mathbb{E}[Q_{s,k,t}(z, \bar{x})]}{\inf_{t \in \mathbb{Z}} a_0(t)} = K \frac{Q_{s,k,t}(1_{k-1}, \bar{x})}{\inf_{t \in \mathbb{Z}} a_0(t)}.
\]

We now find a bound for \( Q_{s,k,t} \). By definition of \( Q_{s,k,t} \) in (15) and using the matrix norm
inequality \[ |A|_1 \leq K\|A\|_{\text{spec}}\|\mathbf{z}\| \] (\(\|\cdot\|_{\text{spec}}\) is the spectral norm) we have

\[
Q_{s,k,t}(1_{k-1}, \mathbf{z}) = \sum_{i=s+1}^{p} a_i(t + k + s) \left[ A_{t+k+s-i} \sum_{r=1}^{k+s-i} \prod_{d=0}^{k-1} A_{t+k+s-i-d} \right] \mathbf{z}_i
\]

\[
\leq \frac{K}{\inf_{t \in \mathbb{Z}} a_0(t)} \sum_{i=s}^{p} a_i(t + k + s) \|A_{t+k+s-i}\|_{\text{spec}} \|\mathbf{z}\|.
\]

To bound the above, we note that by Assumption 3.1(i), \(\sup_{t \in \mathbb{Z}} \sum_{j=1}^{p} a_j(t) \leq (1 - \delta)\), therefore there exists a \(\tilde{\delta}\), where \(0 < \tilde{\delta} < \delta < 1\), such that for all \(t\) we have \(\|A_{t+k+s-i}(\prod_{d=0}^{k-1} A_{t+k+s-i-d})\|_{\text{spec}} \leq K(1 - \tilde{\delta})^{k+1}\), for some finite \(K\). Altogether this gives

\[
Q_{s,k,t}(1_{k-1}, \mathbf{z}) \leq \frac{K}{\inf_{t \in \mathbb{Z}} a_0(t)} \sum_{i=s}^{p} a_i(t + k + s) (1 - \tilde{\delta})^{k+s-i} \|\mathbf{z}\|. \tag{62}
\]

Substituting the above into (61) gives (19).

We now prove (20). We use the same proof to show (60), but apply (58) instead of (59) to obtain

\[
\sup_{z_{-1} \in \mathbb{R}^+} \int \sup_{z \in \mathcal{E}} D_{s,k,t}(y_s | y_{s-1}, \tilde{z}, \mathbf{z}) dy_s \leq \frac{K}{\inf_{t \in \mathbb{Z}} a_0(t)} \sup_{z \in \mathcal{E}} Q_{s,k,t}(\tilde{z}, \mathbf{z}).
\]

By substituting the above into (18) and using the same proof to prove (19) we obtain

\[
\sum_{s=0}^{p-1} \prod_{i=1}^{k-1} f(z_i) \sup_{y_{-1} \in \mathbb{R}^+} \left\{ \int_{\mathbb{R}^+} \sup_{z \in \mathcal{E}} D_{s,k,t}(y_s | y_{s-1}, \tilde{z}, \mathbf{z}) dy_s \right\} d\tilde{z} \leq K \frac{\mathbb{E}[\sup_{z \in \mathcal{E}} Q_{s,k,t}(Z, \mathbf{z})]}{\inf_{t \in \mathbb{Z}} a_0(t)}. \tag{63}
\]

Since \(Q_{s,k,t}(Z, \mathbf{z})\) is a positive function and \(\sup_{z \in \mathcal{E}} Q_{s,k,t}(Z, \mathbf{z}) = Q_{s,k,t}(Z, \eta)\), we have \(\mathbb{E}[\sup_{z \in \mathcal{E}} Q_{s,k,t}(Z, \mathbf{z})] = \sup_{z \in \mathcal{E}} \mathbb{E}[Q_{s,k,t}(Z, \mathbf{z})]\), hence by using (62) we have

\[
\frac{\mathbb{E}[\sup_{z \in \mathcal{E}} Q_{s,k,t}(Z, \mathbf{z})]}{\inf_{t \in \mathbb{Z}} a_0(t)} \leq K(1 - \tilde{\delta})^k \|\mathbf{z}\|.
\]

Substituting the above into (63) gives (20). \(\square\)
A.3 Proofs in Section 4

PROOF of Lemma 4.1 We first observe from (21) and the definition of $d_k$ that

$$X_k = Z_k [a_0 + \sum_{j=1}^{k-1} a_j X_{k-j} + d_k(X)].$$

(64)

Therefore $X_1 = Z_1 [a_0 + d_1(X)]$, which we use to obtain $X_2 = Z_2 [a_0 + a_1 X_1 + d_2(X)] = Z_2 [a_0 + a_0 a_1 Z_1 + a_1 Z_1 d_1(X) + d_2(X)]$. Continuing the iteration we get the general expansion in (22). To prove the recursion

$$Q_{0,k}(Z, X) = \sum_{j=1}^{k} a_j Q_{0,k-j}(Z, X) Z_{k-j} + d_k(X),$$

(65)

we substitute the representation $X_k = \mathcal{P}_{0,k}(Z) Z_k + \mathcal{Q}_{0,k}(Z, X) Z_k$ into (64). By using proof by induction it is straightforward to show that $Q_{0,k}(Z, X)$ satisfies the recursion.

PROOF of Lemma 4.2 Using (21) and (22) we have

$$X_{k+s} = Z_{k+s} \left[ a_0 + \sum_{j=1}^{s} a_j X_{k+s-j} + \sum_{j=s+1}^{k+s-1} a_j X_{k+s-j} + d_{k+s}(X) \right]$$

$$= Z_{k+s} \left\{ a_0 + \sum_{j=1}^{s} a_j X_{k+s-j} + \sum_{j=s+1}^{\infty} a_j Z_{k+s-j} \mathcal{P}_{0,k+s-j}(Z) + \sum_{j=s+1}^{k+s} a_j Z_{k+s-j} \mathcal{Q}_{0,k+s-j}(Z, X) \right\} + d_{k+s}(X)$$

$$= Z_{k+s} \left\{ \mathcal{P}_{s,k}(Z) + \mathcal{Q}_{s,k}(Z, X) \right\},$$

where $\mathcal{Q}_{s,k}$ and $\mathcal{P}_{s,k}$ are defined in (25), thus giving us the desired result.

PROOF of Lemma 4.3. We first prove

$$(1 - \sum_{j=1}^{\infty} a_j z^j)^{-1} = \sum_{j=0}^{\infty} \psi_j z^j.$$  

(66)

Let $a(z) = 1 - \sum_{j=1}^{\infty} a_j z^j$, since the coefficients of $a(z)$ are absolutely summable, $a(z)$ is analytic. Because $\sum_{j=1}^{\infty} a_j < 1 - \delta$, for all $|z| \leq 1$ we have $|\sum_{j=1}^{\infty} a_j z^j| \leq 1 - \delta$, thus $|a(z)| \geq 1 - |\sum_{j=1}^{\infty} a_j z^j| \geq \delta > 0$, which means that $a(z)$ is not zero inside the unit circle. This means
that for $|z| \leq 1$, $a(z)$ has a reciprocal and there exists coefficients $\{\psi_j\}$ such that (66) is true. Furthermore, Hannan and Kavaliers (1986) show if $\sum_j |j^\alpha a_j| < \infty$, then $\sum_j |j^\alpha |\psi_j| < \infty$. We now prove (27) by using the recursion

$$Q_{s,k}(1_{k-1}, z) = \sum_{j=1}^{k} a_{j+s} Q_{0,k-j}(1_{k-j-1}, z) + d_{k+s}(z), \quad s \geq 0. \quad (67)$$

We observe that by using the above and setting $Q_{0,k}(1_{k-1}, z) = 0$ for $k \leq 0$, we have that $Q_{0,k}(1_{k-1}, z)$ satisfies

$$Q_{0,k}(1_{k-1}, z) = \sum_{j=1}^{\infty} a_j Q_{0,k-j}(1_{k-j-1}, z) + d_k(X), \quad k > 0.$$

Rewriting the above using backshift notation we have $a(B)Q_{0,k}(1_{k-1}, X) = d_k(X)$, where $B$ is the backshift operator. Since the reciprocal of $a(z)$ is well defined for $|z| \leq 1$, we have $Q_{0,k}(1_{k-1}, X) = a(B)^{-1}d_k(X) = \sum_{j=0}^{\infty} \psi_j d_{k-j}(X) = \sum_{j=0}^{k-1} \psi_j d_{k-j}(X)$, and thus we obtain the desired result. \[\square\]

**PROOF of Lemma 4.4** Using the density of $f_{s,k}$ derived in (26) and the same method to prove (60) we have

$$\int \prod_{i=1}^{k-1} f_Z(z_i) \left\{ \int |f_{0,k}(y,z,x) - f_{0,k}(y,\bar{z},0)|dy \right\} d\bar{z} \leq K \int \prod_{i=1}^{k-1} f_Z(z_i) \frac{Q_{0,k}(\bar{z}, x)}{a_0} d\bar{z} \leq K \int \prod_{i=1}^{k-1} f_Z(z_i) \frac{Q_{0,k}(\bar{z}, x)}{a_0} d\bar{z} \leq K \frac{a_0}{a_0} \mathbb{E}[Q_{0,k}(Z, x)].$$

By noting that $\mathbb{E}[Q_{0,k}(Z, x)] = Q_{0,k}(1_{k-1}, x)$ and using (27) gives us (28).

To prove (29) we use (26) and the same method used to prove (60), this gives us

$$\int \prod_{i=1}^{k-1} f_Z(z_i) \left\{ \sup_{y_{s-1} \in \mathbb{R}^s} \int \mathcal{D}_{s,k}(y_s|y_{s-1}, x)dy_s \right\} d\bar{z} \leq K \frac{a_0}{a_0} \mathbb{E}[Q_{s,k}(Z_{k-1}, x)] = K \frac{a_0}{a_0} Q_{s,k}(1_{k-1}, x).$$

29
By substituting (67) and (27) into the above we have

\[
\int \prod_{i=1}^{k-1} f(z_i) \left\{ \sup_{y_{s-1} \in \mathbb{R}^s} \int D_{s,k}(y_s, y_{s-1}, z_i, \bar{x}) dy_s \right\} dz
\]

\[
\leq \frac{1}{a_0} \left\{ \sum_{j=s+1}^{k+s} a_j Q_{0, k+j, j}(1, \bar{x}, \bar{x}) + d_{k+j, j}(\bar{x}) \right\} \leq \frac{1}{a_0} \left\{ \sum_{j=s+1}^{k+s} a_j \sum_{l=0}^{k+s-j} |\psi_l| d_{k+s-j-l, j}(\bar{x}) + d_{k+s, j}(\bar{x}) \right\}
\]

which gives us (29).

The proof of (30) is very similar to the proof of (29), but uses Assumption 3.1(iv) rather than Assumption 3.1(iii), we omit the details.

\[\Box\]

**PROOF of Lemma 4.5** First let us consider the function \( h(\eta) = c\eta + d\eta^{-\nu} \), it clear that \( h(\cdot) \) is a convex function with a unique minimum at \( \eta^* = \left( \frac{d}{c} \right)^{\frac{1}{\nu+1}} \), where \( h(\eta^*) = (\nu+1) \left( \frac{d}{c} \right)^{\frac{1}{\nu+1}} \). It is straightforward to extend this argument to the function \( \sum_{i=0}^{\infty} (c_i \eta_{-i} + d_i \eta_{-i}^{-\nu}) \), which gives the required result.

\[\Box\]

**PROOF of Theorem 4.1(i)** By substituting \( a_j \sim j^{-\delta} \) and \( |\psi_j| \sim j^{-\delta} \) into (33) and using for \( 0 < \beta \leq 1 \), that \( (\sum_i g_i)^\beta \leq \sum_i g_i^\beta \), and setting \( \beta = \frac{\nu}{\nu+1} \) we have

\[
\sup_{G \in \mathcal{G}(\sum_i g_i)} \left| P(G \cap H) - P(G)P(H) \right| \leq K \sum_{i=0}^{\infty} \left[ \sum_{s=0}^{\infty} \sum_{j=s+1}^{k+s} (j + 1)^{-\delta} \sum_{l=0}^{k+s-j} (l + 1)^{-\delta} (k + s - j - l + i + 1)^{-\delta} + \sum_{s=0}^{\infty} (k + s + i + 1)^{-\delta} \right]^{\frac{1}{\nu+1}}
\]

\[
\leq K \sum_{s=0}^{\infty} \sum_{j=s+1}^{k+s} [(j + 1)(k + s - j + 1)]^{\tilde{\delta}+2} + (k + 1)^{\tilde{\delta}+2}
\]

where \( K \) is a finite constant which depends on \( \mathbb{E}|X_t|^\nu \) and \( \nu \), and \( \tilde{\delta} = \delta \times \left( \frac{\nu}{\nu+1} \right) \). We note that \( f(j) = (j + 1)(k + s - j + 1) \) is a concave quadratic in \( j \), which takes a maximum at either
boundary \((k + s + 1)\) and \((s + 2)k\). Using this and \((s + 2)k \geq (k + s + 1)\) we have

\[
\sup_{\substack{G \in \sigma(\sum_{n=0}^{k}) \\ H \in \sigma(\sum_{n=0}^{\infty})}} |P(G \cap H) - P(G)P(H)| \\
\leq K \sum_{s=0}^{\infty} k(k + s + 1)^{-\delta+2} + (k + 1)^{-\delta+2} \leq K \left[ k(k + 1)^{-\delta+3} + (k + 1)^{-\delta+2} \right],
\]

which proves Theorem 4.1(i).
